

Roof Blisters 101: What to look for

- Excessive moisture
- Poor ventilation
- Poor roof installation

If you leave a roof blister untreated, it will grow larger as more moisture gets inside, which can lead to you requiring more extensive repairs or possible replacement to fix the issue. Much like a blister on your hand, you cannot pop a roof blister because it can lead to additional issues, like leaking with your roof. It is crucial to have a qualified commercial roofing expert address these concerns.

Having a maintenance contract with a trusted company will ensure that your roof is regularly inspected, and any damage or issues such as roof blisters are addressed before major damage occurs to your substrate or facility. Roof blisters that contain air are technically keeping moisture out of the substrate and could be left alone, but other roof blisters such as those in seams, high traffic areas, or those with breaks that can admit moisture will need to be repaired.

This type of blistering can be hazardous and very costly. It can happen quickly. Especially if you haven't had a roof inspection in some time. It's important to catch these types of damages because they normally result costly repairs.
